  ggplot(aes(level_type)) +
  geom_bar() +
  facet_wrap(~grouping_var, scales = "free")
```

Does a model that includes study_type explain the variance better than one that does not?

We will use an lmer model from the lme4 package, because we we are interested in the effects of study_type, and not the individual differences that we can not control for. The intercept of each individual (id) will be defined as a random effect. We will leave out the NA's.

Furthermore, word_pair will be defined as a random effect. At this moment we are mainly interested in whether study_type explains differences in relatedness in general. We don't want to look at the effect of study_type on the relatedness ratings of each word_pair.

The null-model

The null-model only includes the intercept for each word_pair and the intercept of each individual as a random effects.

```
df_naomit <- df %>% na.omit

model0 <- lmer(relatedness ~ (1|word_pair) + (1|id), data = df_naomit, REML = F)</pre>
```

The alternative model (includes study_type)

In the table we can see that there is a relatively large difference between the ratings of people with a gamma background and those with an alpha background. estimate > (Intercept) gives us the relatedness intercept of relatedness of people with an alpha background. The estimate value at study_typebeta gives the difference with this intercept. The same holds for study_typegamma.

```
model1 <- lmer(relatedness ~ study_type + (1|word_pair) + (1|id), data = df_naomit, REML = F)
model1 %>%
   tidy() %>%
   rename("t-value" = statistic) %>%
   select(-group) %>%
   kable()

## Warning in bind_rows_(x, .id): binding factor and character vector,
## coercing into character vector
```

Warning in bind_rows_(x, .id): binding character and factor vector,
coercing into character vector

term	estimate	std.error	t-value
(Intercept)	5.1809524	0.6147807	8.4273179
study_typebeta	-0.1349206	0.2751886	-0.4902842
$study_typegamma$	-0.9517857	0.3263336	-2.9166038
$sd_(Intercept).id$	0.5345427	NA	NA
$sd_(Intercept).word_pair$	3.1039912	NA	NA
$sd_Observation. Residual$	1.8317224	NA	NA

Does the alternate model explain significantly more of the variance?

The p-value indicates that a model that includes study_type explains significantly more of the variance.

```
anova(model0, model1)
```

```
## Data: df_naomit
## Models:
## model0: relatedness ~ (1 | word_pair) + (1 | id)
## model1: relatedness ~ study_type + (1 | word_pair) + (1 | id)
## Df AIC BIC logLik deviance Chisq Chi Df Pr(>Chisq)
## model0 4 4574.1 4594.1 -2283.1 4566.1

## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

How about level and duration and combinations of those and study_type?

```
model2 <- lmer(relatedness ~ level + (1|word_pair) + (1|id), data = df_naomit, REML = F)
model3 <- lmer(relatedness ~ duration + (1|word_pair) + (1|id), data = df_naomit, REML = F)</pre>
```

level

```
anova(model0, model2)
```

duration

```
anova(model0, model3)

## Data: df_naomit

## Models:

## model0: relatedness ~ (1 | word_pair) + (1 | id)

## model3: relatedness ~ duration + (1 | word_pair) + (1 | id)

## Df AIC BIC logLik deviance Chisq Chi Df Pr(>Chisq)

## model0 4 4574.1 4594.1 -2283.1 4566.1

## model3 5 4576.1 4601.0 -2283.0 4566.1 0.0275 1 0.8683
```

Models including level xor duration do not explain significantly more of the variance than models that do not include these.

Correlations

Between participants

Are there any correlations between participants higher than .9? And lower tha .5?

corr %>%
filter(correlation > .9) %>%
